

## Keywords

Keyword	Description	Code Examples
False, True	Boolean data type	<pre>False == (1 &gt; 2) True == (2 &gt; 1)</pre> 
and, or, not	Logical operators → Both are true → Either is true → Flips Boolean	<pre>True and True    # True True or False    # True not False        # True</pre>
break	Ends loop prematurely	<pre>while True:     break # finite loop</pre>
continue	Finishes current loop iteration	<pre>while True:     continue print("42") # dead code</pre>
class	Defines new class	<pre>class Coffee:     # Define your class</pre>
def	Defines a new function or class method.	<pre>def say_hi():     print('hi')</pre>
if, elif, else	Conditional execution: - "if" condition == True? - "elif" condition == True? - Fallback: else branch	<pre>x = int(input("ur val:")) if x &gt; 3: print("Big") elif x == 3: print("3") else: print("Small")</pre>
for, while	<pre># For loop for i in [0,1,2]:     print(i)</pre>	<pre># While loop does same j = 0 while j &lt; 3:     print(j); j = j + 1</pre> 
in	Sequence membership	<pre>42 in [2, 39, 42] # True</pre>
is	Same object memory location	<pre>y = x = 3 x is y    # True [3] is [3] # False</pre>
None	Empty value constant	<pre>print() is None # True</pre>
lambda	Anonymous function	<pre>(lambda x: x+3)(3) # 6</pre> 
return	Terminates function. Optional return value defines function result.	<pre>def increment(x):     return x + 1 increment(4) # returns 5</pre>

## Basic Data Structures

Type	Description	Code Examples
Boolean	<p>The Boolean data type is either <b>True</b> or <b>False</b>. Boolean operators are ordered by priority: <b>not</b> → <b>and</b> → <b>or</b></p> <p><code>{ }</code> → </p> <p><code>{ 1, 2, 3 }</code> → </p>	<pre>## Evaluates to True: 1&lt;2 and 0&lt;=1 and 3&gt;2 and 2&gt;=2 and 1==1 and 1!=0  ## Evaluates to False: bool(None or 0 or 0.0 or '' or [] or {} or set())</pre> <p><b>Rule:</b> <i>None, 0, 0.0, empty strings, or empty container types evaluate to False</i></p>
Integer, Float	<p>An <b>integer</b> is a positive or negative number without decimal point such as 3.</p> <p>A <b>float</b> is a positive or negative number with floating point precision such as 3.1415926.</p> <p><b>Integer division</b> rounds toward the smaller integer (example: <code>3//2==1</code>).</p>	<pre>## Arithmetic Operations x, y = 3, 2 print(x + y)      # = 5 print(x - y)      # = 1 print(x * y)      # = 6 print(x / y)      # = 1.5 print(x // y)     # = 1 print(x % y)      # = 1 print(-x)         # = -3 print(abs(-x))    # = 3 print(int(3.9))   # = 3 print(float(3))   # = 3.0 print(x ** y)     # = 9</pre>
String	<p>Python Strings are sequences of characters.</p> <p><b>String Creation Methods:</b></p> <ol style="list-style-type: none"> <li>Single quotes <code>&gt;&gt;&gt; 'Yes'</code></li> <li>Double quotes <code>&gt;&gt;&gt; "Yes"</code></li> <li>Triple quotes (multi-line) <code>&gt;&gt;&gt; """Yes We Can"""</code></li> <li>String method <code>&gt;&gt;&gt; str(5) == '5'</code> True</li> <li>Concatenation <code>&gt;&gt;&gt; "Ma" + "hatma"</code> 'Mahatma'</li> </ol> <p><b>Whitespace chars:</b> Newline <code>\n</code>, Space <code>\s</code>, Tab <code>\t</code></p>	<pre>## Indexing and Slicing s = "The youngest pope was 11 years" s[0] # 'T' s[1:3] # 'he' s[-3:-1] # 'ar' s[-3:] # 'ars'</pre> <p><b>Slice [::2]</b></p> <pre>x = s.split() x[-2] + " " + x[2] + "s" # '11 popes'</pre> <pre>## String Methods y = " Hello world\t\n " y.strip() # Remove Whitespace "HI".lower() # Lowercase: 'hi' "hi".upper() # Uppercase: 'HI' "hello".startswith("he") # True "hello".endswith("lo") # True "hello".find("ll") # Match at 2 "cheat".replace("ch", "m") # 'meat' ''.join(["F", "B", "I"]) # 'FBI' len("hello world") # Length: 15 "ear" in "earth" # True</pre>

## Complex Data Structures

Type	Description	Example
List	Stores a sequence of elements. Unlike strings, you can modify list objects (they're <i>mutable</i> ).	<pre>l = [1, 2, 2] print(len(l)) # 3</pre> 
Adding elements	Add elements to a list with (i) <code>append()</code> , (ii) <code>insert()</code> , or (iii) list concatenation.	<pre>[1, 2].append(4) # [1, 2, 4] [1, 4].insert(1,9) # [1, 9, 4] [1, 2] + [4] # [1, 2, 4]</pre>
Removal	Slow for lists	<pre>[1, 2, 2, 4].remove(1) # [2, 2, 4]</pre>
Reversing	Reverses list order	<pre>[1, 2, 3].reverse() # [3, 2, 1]</pre>
Sorting	Sorts list using fast Timsort	<pre>[2, 4, 2].sort() # [2, 2, 4]</pre>
Indexing	Finds the first occurrence of an element & returns index. Slow worst case for whole list traversal.	<pre>[2, 2, 4].index(2) # index of item 2 is 0 [2, 2, 4].index(2,1) # index of item 2 after pos 1 is 1</pre>
Stack	Use Python lists via the list operations <code>append()</code> and <code>pop()</code>	<pre>stack = [3] stack.append(42) # [3, 42] stack.pop() # 42 (stack: [3]) stack.pop() # 3 (stack: [])</pre>
Set	An unordered collection of unique elements ( <i>at-most-once</i> ) → fast membership $O(1)$	<pre>basket = {'apple', 'eggs',           'banana', 'orange'} same = set(['apple', 'eggs',            'banana', 'orange'])</pre>

Type	Description	Example
Dictionary	Useful data structure for storing (key, value) pairs	<pre>cal = {'apple' : 52, 'banana' : 89,        'choco' : 546} # calories</pre>
Reading and writing elements	Read and write elements by specifying the key within the brackets. Use the <code>keys()</code> and <code>values()</code> functions to access all keys and values of the dictionary	<pre>print(cal['apple'] &lt; cal['choco']) # True cal['cappu'] = 74 print(cal['banana'] &lt; cal['cappu']) # False print('apple' in cal.keys()) # True print(52 in cal.values()) # True</pre>
Dictionary Iteration	You can access the (key, value) pairs of a dictionary with the <code>items()</code> method.	<pre>for k, v in cal.items():     print(k) if v &gt; 500 else '' # 'choco'</pre>
Membership operator	Check with the <code>in</code> keyword if set, list, or dictionary contains an element. Set membership is faster than list membership.	<pre>basket = {'apple', 'eggs',           'banana', 'orange'} print('eggs' in basket) # True print('mushroom' in basket) # False</pre>
List & set comprehension	List comprehension is the concise Python way to create lists. Use brackets plus an expression, followed by a <code>for</code> clause. Close with zero or more <code>for</code> or <code>if</code> clauses. Set comprehension works similar to list comprehension.	<pre>l = ['hi ' + x for x in ['Alice',                         'Bob', 'Pete']] # ['Hi Alice', 'Hi Bob', 'Hi Pete']  l2 = [x * y for x in range(3) for y       in range(3) if x&gt;y] # [0, 0, 2]  squares = { x**2 for x in [0,2,4]             if x &lt; 4 } # {0, 4}</pre>
