

Python Cheat Sheet: Complex Data Types

"A puzzle a day to learn, code, and play"

| | Description | Example |
|------------------------------------|---|---|
| List | A container data type that stores a sequence of elements. Unlike strings, lists are mutable: modification possible. | <pre>1 = [1, 2, 2] print(len(1)) # 3</pre> |
| Adding elements | Add elements to a list with (i) append, (ii) insert, or (iii) list concatenation. The append operation is very fast. | [1, 2, 2].append(4) # [1, 2, 2, 4] [1, 2, 4].insert(2,2) # [1, 2, 2, 4] [1, 2, 2] + [4] # [1, 2, 2, 4] |
| Removal | Removing an element can be slower. | [1, 2, 2, 4].remove(1) # [2, 2, 4] |
| Reversing | This reverses the order of list elements. | [1, 2, 3].reverse() # [3, 2, 1] |
| Sorting | Sorts a list. The computational complexity of sorting is superlinear in the no. list elements. | [2, 4, 2].sort() # [2, 2, 4] |
| Indexing | Finds the first occurrence of an element in the list & returns its index. Can be slow as the whole list is traversed. | [2, 2, 4].index(2) # index of element 2 is "0" [2, 2, 4].index(2,1) # index of el. 2 after pos 1 is "1" |
| Stack | Python lists can be used intuitively as stacks via the two list operations append() and pop(). | <pre>stack = [3] stack.append(42) # [3, 42] stack.pop() # 42 (stack: [3]) stack.pop() # 3 (stack: [])</pre> |
| Set | A set is an unordered collection of unique elements ("at-most-once"). | <pre>basket = {'apple', 'eggs', 'banana', 'orange'} same = set(['apple', 'eggs', 'banana', 'orange'])</pre> |
| Dictionary | The dictionary is a useful data structure for storing (key, value) pairs. | calories = {'apple' : 52, 'banana' : 89, 'choco' : 546} |
| Reading and writing elements | Read and write elements by specifying the key within the brackets. Use the keys() and values() functions to access all keys and values of the dictionary. | <pre>print(calories['apple'] < calories['choco']) # True calories['cappu'] = 74 print(calories['banana'] < calories['cappu']) # False print('apple' in calories.keys()) # True print(52 in calories.values()) # True</pre> |
| Dictionary Looping | You can access the (key, value) pairs of a dictionary with the items() method. | <pre>for k, v in calories.items(): print(k) if v > 500 else None # 'choco'</pre> |
| Membership operator | Check with the 'in' keyword whether the set, list, or dictionary contains an element. Set containment is faster than list containment. | <pre>basket = {'apple', 'eggs', 'banana', 'orange'} print('eggs' in basket) # True print('mushroom' in basket) # False</pre> |
| List and Set Comprehens ion | List comprehension is the concise Python way to create lists. Use brackets plus an expression, followed by a for clause. Close with zero or more for or if clauses. Set comprehension is similar to list | <pre># List comprehension l = [('Hi ' + x) for x in ['Alice', 'Bob', 'Pete']] print(l) # ['Hi Alice', 'Hi Bob', 'Hi Pete'] l2 = [x * y for x in range(3) for y in range(3) if x>y] print(l2) # [0, 0, 2] # Set comprehension</pre> |
